1

Urbanization

Urbanization leads to removal of the vegetation, more impervious surfaces, smoother surfaces, outlined water ways etc. i.e. quicker runoff

Hydrologic cycle of the natural environment

Hydrologic cycle of the urban environment

McCuen R.H. (1998)

Global challenge

Referring to UN – UNESCO the people are facing:

1. Growth in population
2. Growth in urbanization
3. Growth in lack of water supply and wastewater services , mostly in developing countries
4. Climate changes

The population in the World passed in 6.5 billion in February 2006

People need:

- Clean water ([Water Supply](#))
- Proper sanitary conditions ([wastewater disposal](#))
- Protection against flooding (good [stormwater management](#))

3

Urbanization (U) and Urban Hydrology (UH)

Urbanization is one of the most important trends of the twenty-first century.

When a rural area is a subject to urbanization, changes in the flow regime will occur

The urbanization seems to create two major hydrologic challenges to urban drainage:

Flood control i.e. the prevention of flooding within and downstream urban areas

Pollution control i.e. disposal of waterborne wastes from urban areas without impairing the quality of local watercourses.

NTNU I

5

Effects of increased air temperature

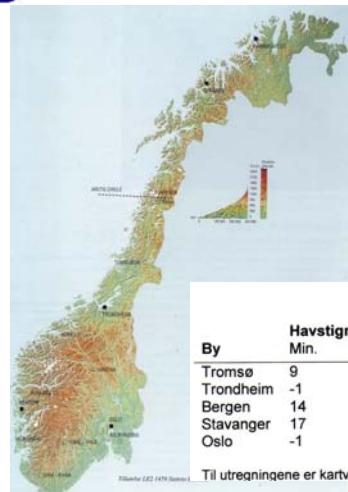

1. There will be wetter and wilder weather (at our latitude)
That gives higher depth of precipitation and higher intensities
2. Icecaps will melt
The icecap on Greenland, in Antarctic, Himalaya, and glaciers in Iceland and Norway will disappear
3. The sea level will rise
because of increased runoff from melt water and volume increase by higher temperature

7

The effects of urbanization on urban runoff

1. Removing vegetation and lining surfaces
2. Impervious areas (roads, streets, parking places etc.) are constructed
3. Quicker stormwater runoff and higher peaks
4. Groundwater table may be lowered and the vegetation will be degraded

Paving and construction of stormwater pipes and a quick conveyance of stormwater may lead to dramatic changes in the water circle

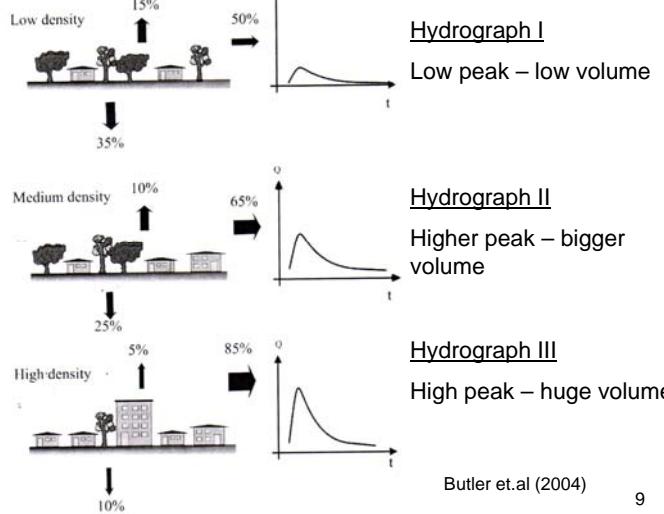

Thorolfsson (1988)

10

The objective of the urban drainage system

The objective of urban drainage system (UDS) is to collect wastewater, stormwater, illegal water etc., where it is generated, dispose it locally or transport it away, treat it if required and finally discharge it into an appropriate and an approved recipient, without loss of pollutants. And at acceptable costs

The total discharges from treatment plants and CSO including emergency CSO, leakages etc. is to be quantified, and the total amount of pollutants discharged from UDS to the nature is to know:

"Total discharges"

NTNU

11

The objective of the sewer system

The objective of the sewer system is to collect all unwanted water (foul water and stormwater) where it is generated, dispose it locally or transport it away, treat it if required and to discharge it to an approved recipient, with out loss of pollutants and at acceptable costs

It means optimizing of the system regarding hydraulic, pollution discharges and economy.

This require use of EDB based runoff models such as **MOUSE, SWMM, NIVANETT** etc.

Plus time data sets for long periods from urban hydrological measuring stations , GIS (or a map) and data communication.

12

From wastewater to stormwater oriented drainage plans

During the last 40 – 50 years we have been working on cleaning up regarding municipal sewage discharges

It has been especially the point discharges for foul water, that has been in focus because of hygienic considerations (bacteria viruses etc.).

Very costly facilities to collect, transport and treat foul water have been built

New it is turn for the stormwater

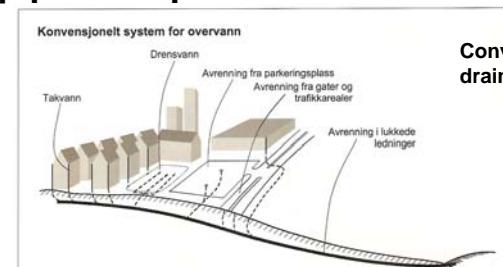

Stormwater is coming from precipitation i.e. rainfall snowmelt etc is much more difficult to handle because of it is stochastic processes and discharges are both point discharges and diffuse discharges

15

The transportation system

- Sewer pipes lines (free surface flow, but surcharge may occur) and pressured flow (siphons, pumping lines, discharge outlets etc)
- Sewer tunnels
- **CSO (Combined sewer overflows)**
- Detention facilities
- Pumping stations and pumping pipe lines
- Discharge arrangements (Outlets)

18

Examples on CSO Radiation driven CSO

It is no rainfall
The CSO is caused by melting driven by positive temperature and radiation

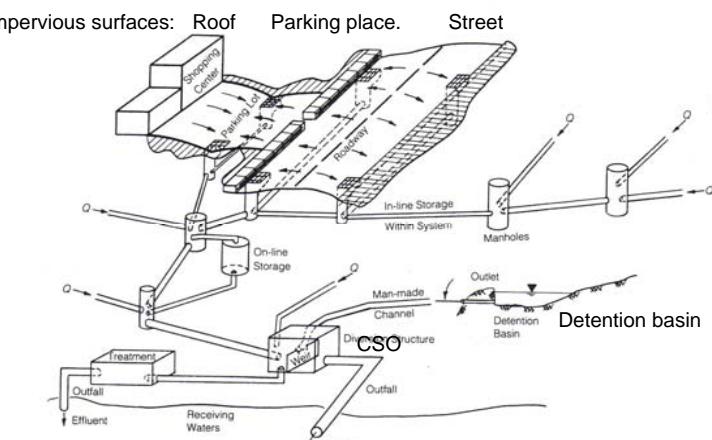

CSO discharge into Nidelva River from Fredlybekken basin (550ha)

Categorization of facilities for open storm drainage (OSD) (Stahre 2006)

Stahre (2006)

Examples on technical solutions within the four categories

Category	Examples of technical configuration
Source control (private land)	Roofs with vegetation cover (moss/sedum) Infiltration on lawns Permeable paving Infiltration in stone fillings (percolation) Local ponds Collection and recycling of roof runoff for irrigation, toilet flushing, etc.
Onsite control (public land)	Permeable paving Filter strips Temporary flooding onto especially prepared surfaces Ponds
Slow transport (public land)	Swales i.e. vegetated surfaces Greeks/ditches Channels
Downstream control (public land)	Large ponds Wetlands Lakes

Pollution in Stormwater

An example form a parking place near a shopping center in Seattle, USA

In addition to common water polluting matters, SS, COD etc, stormwater may contain micro pollutants such as heavy metals; Pb, Cu, Cr, Hg, etc. and organic micro pollutants such as PAH, PCB etc.

That may be harmful to aquatic resources humans and other living beings

Pollution in snow becomes stormwater pollution while melting

At Risvollan, Trondheim in April 1993
Trondheim

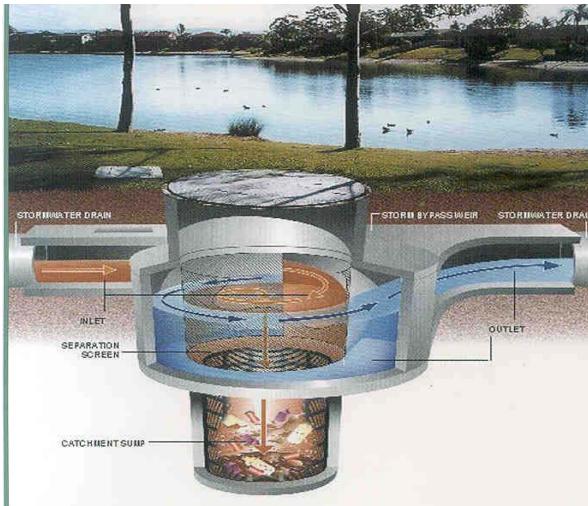

Snow dump at Byåsen in

The snow may contain polluting matters as found in stormwater, also heavy metals as Pb, Cu, Cr, Zn, Hg, etc. and organic micro pollutants as PAH, PCB, etc. Salt (NaCl) may be found in it too

The LID - concept

LID-concept is developed in USA,
originally to be used in temperate climate

LID-concept is an approach to stormwater management,
where we by use of hydrology orientated area planning
and sets of integrated management methods try to
minimize the effect of man made efforts on the original
hydrological situation.

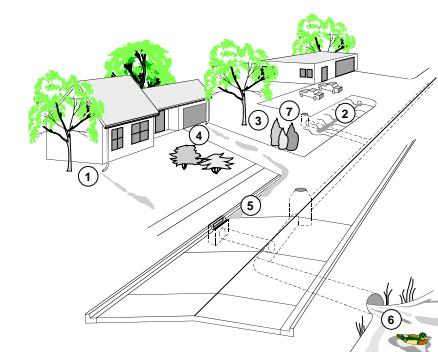

LID-concept tries to mimic the conditions before
urbanization by compensate for disappearance of natural
water ways for the rain water, by maintain infiltration,
evapotranspiration and depression storage, and in
addition to increase the runoff time for stormwater and
avoid storage of surplus water, PGDER (1999)

31

Open stormwater systems and vegetation

BMP-SYSTEM

- ① Regnvann direkte til plen
- ② Vannvei med grøss tillater vann å infiltrere
- ③ Plen

TRADISJONELT SYSTEM

- ④ Regnvann direkte ut på tette bater
- ⑤ Rennstein ledet til overvannsledding
- ⑥ Overvann ledet til innsjø eller elv/bekk
- ⑦ Avrenning fra parkeringsplasser ledet til overvannsledding

Guidelines for climate adjusted stormwater management

The guideline focus on:

Climate changes, local stormwater disposal (LOD) and use of open stormwater solutions such as; constructed channels, ditches, dams and lakes, creeks and rivers in cities

Floodways for stormwater on urban surfaces to handle 100 yr storm

Dimensioning these facilities

See: www.norskvann.no

Measures affecting stormwater runoff

Pollutants in stormwater are often connected to particles
Following treatment methods are actual:

- Stormwater ponds
- Infiltration basins
- Infiltration on green surfaces
- Vegetated surfaces (swales)
- Percolation basins (f. examples underground stone basins),
- Percolation trenches
- Artificial wetlands
- Natural wetlands
- Detention basins
- Oil separation faculties
